NeuroQ™

QUANTITATIVE ANALYSIS FOR NEUROIMAGING TECHNOLOGY

Version 3.0

OVERVIEW

The **NeuroQ™** Display and Analysis Program has been developed to aid in the assessment of human brain scans through quantification of mean pixel values lying within standardized regions of interest, and to provide quantified comparisons with brain scans derived from FDG-PET studies of defined groups having no identified neuropsychiatric disease or symptoms, i.e., asymptomatic controls (AC). The Program provides automated analysis of brain PET scans, with output that includes quantification of relative activity in 240 different brain regions, as well as measures of the magnitude and statistical significance with which activity in each region differs from mean activity values of brain regions in the AC database. The new features of version 3.0 include NeuroQ™ Quality Control Screen, PET/CT display screen, patient study comparison analysis, and EQuAL™ a tool for evaluating temporal lobe Epilepsy. This manual describes the display and analysis features of the Program, and their end-user operation.

Program Description

The NeuroQ™ Program is indicated to:

- 1) assist with regional assessment of human brain scans, through automated quantification of mean pixel values lying within standardized regions of interest (S-ROI's), and
- 2) assist with comparisons of the activity in brain regions of individual scans relative to normal activity values found for brain regions in FDG-PET scans, through quantitative and statistical comparisons of S-ROI's.

The program requires the operator to select the patient's FDG-Brain scan. Following a number of internal checks on the data (e.g., accurate radiopharmaceutical), the operator has to initiate the elastic spatial reformatting or normalization of the patient's scan into a standardized volumetric space. Following this step, the program determines the uptake in 240 ROIs, normalized to the uptake in the subject's sensorimotor cortical region (S-ROI). The uptake in the ROIs is then compared to a normal data base of uptakes, based upon uptake in the corresponding S-ROIs determined in 50 normal subjects without identified neuropsychiatric disease. Any region with an uptake below 1.65 S.D of the mean, established from the normal data base is considered abnormal.

Installation of NeuroQ

The commercial versions of the applications are downloaded from our web site http://www.syntermed.com/downloads_NeuroQ.htm once the software has been purchased the software license is sent to enable the applications. The demo version of NeuroQ can be installed from our Syntermed Demo CD which contains all of our software products. To install from the Demo CD first insert the CD into your drive and the autoplay program will be displayed.

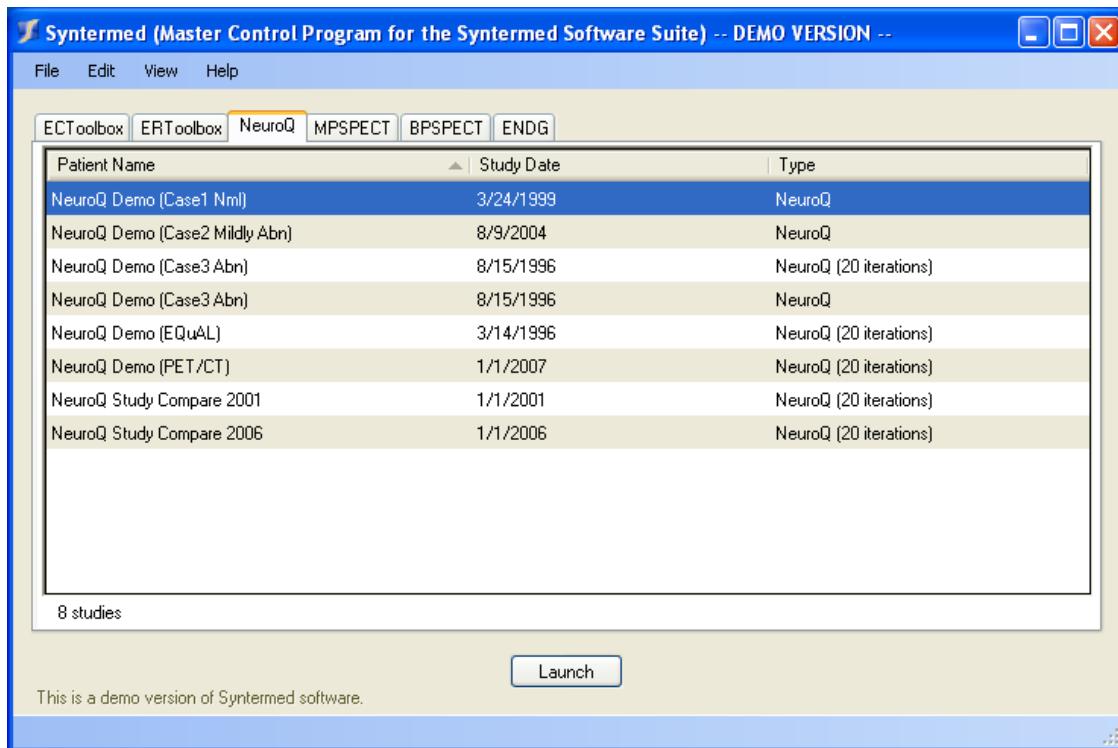

The Autoplay screen should automatically be displayed when the CD is put in the drive. If it does not come up then go to the CD and click on the autorunNCTb.exe file to bring up the screen. Read the Read Me First document and then you can install the applications by clicking on the Install button. If you want to review the user manual then click on the NeuroQ Manual button. You can then run NeuroQ directly from the CD by clicking on the RUN button which will bring up the MCP program listing all of the demo patients.

LAUNCHING THE PROGRAM

- 1) There are multiple ways to launch the NeuroQ program. You can launch it from the Windows operating system by double-clicking on the Syntermed Icon on your desktop (shown on the left), or you can go to the C:\Program Files\Syntermed\Syntermed Demo 2008\MCP folder and double-click on the MCP.exe application.

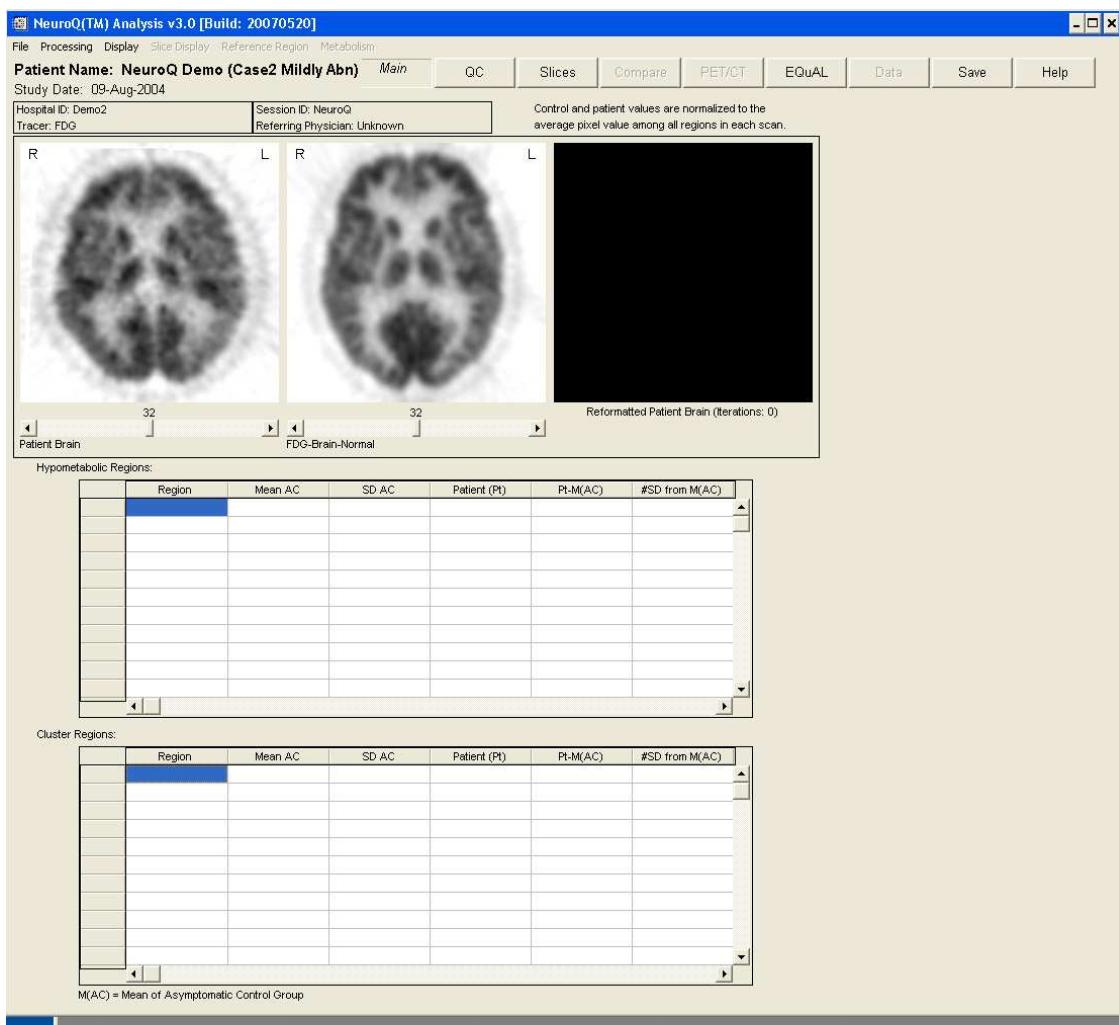

Once MCP is launched the following screen will be displayed:

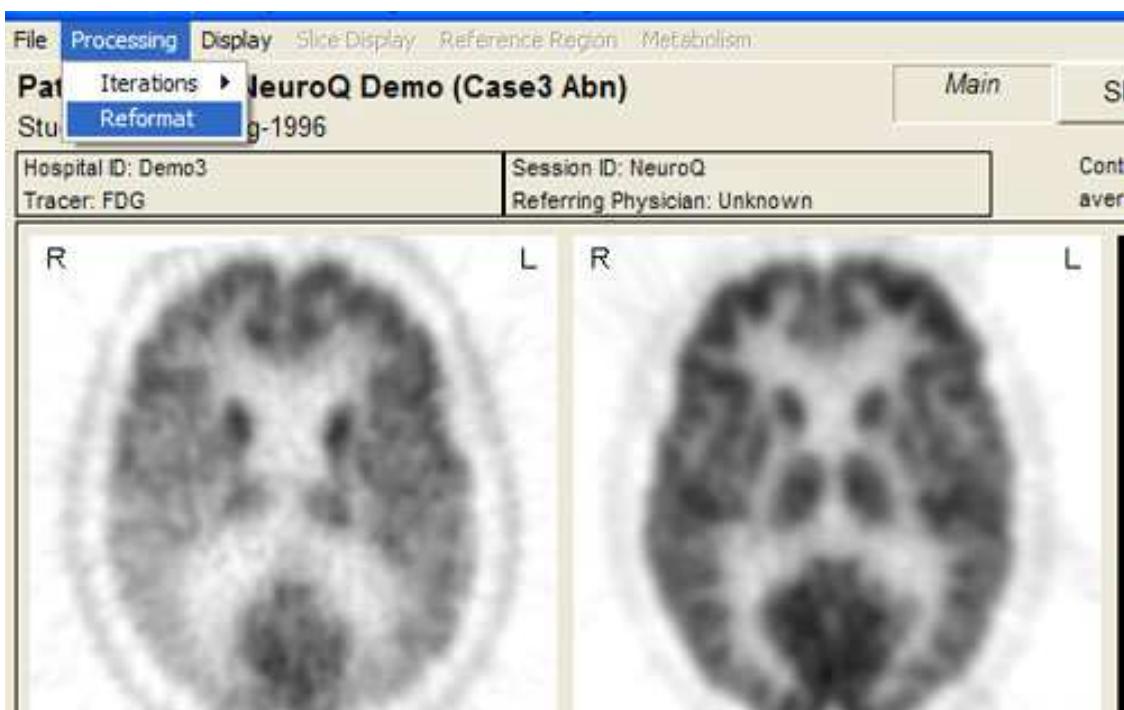

- 2) There are three demo cases numbered 1-3 which have not yet been processed. There is also one study, Demo Case 3, that has already been reformatted that is included in the list and is called NeuroQ (20 iterations). If you select the NeuroQ (20 iterations) study then it will bring up the study that has already been processed. For the other studies you will need to process them. There are also demo cases for EQuAL, PET/CT and Study Comparison.

PROCESSING

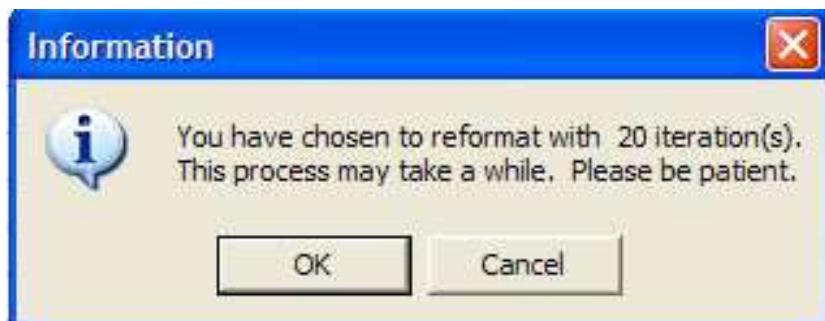

- 3) The PET FDG brain files in DICOM format need to be selected and imported into the NeuroQ program. Once this is done the initial NeuroQ screen will be displayed which is shown below. The image on the left is mid transaxial slice of the patient. The image in the middle represents the mid transaxial slice of the normal template. The normal template images are from a high-quality normal brain FDG PET scan acquired at UCLA and these are the images in which the 240 standardized regions of interest were defined. **Note: The NeuroQ program can only handle brain data sets which contain actual brain data. If slices are submitted to the NeuroQ program for reformatting which are outside of the brain region then including these images along with the images containing brain activity could result in inaccurate results.**

- 4) The patient's transaxial slices must be reformatted to fit the normal template transaxial slices. This is performed from the Processing menu item: select Reformat from the drop down box as shown below. The registration algorithm used for reformatting the patient's data is a robust spatial transformation method published by Henry Huang and Ed Hoffman, along with their collaborators. It was originally described in IEEE (Tai et al., *IEEE Trans. Nucl. Sci.* NS-44 1997; 4: 1606-1612.)

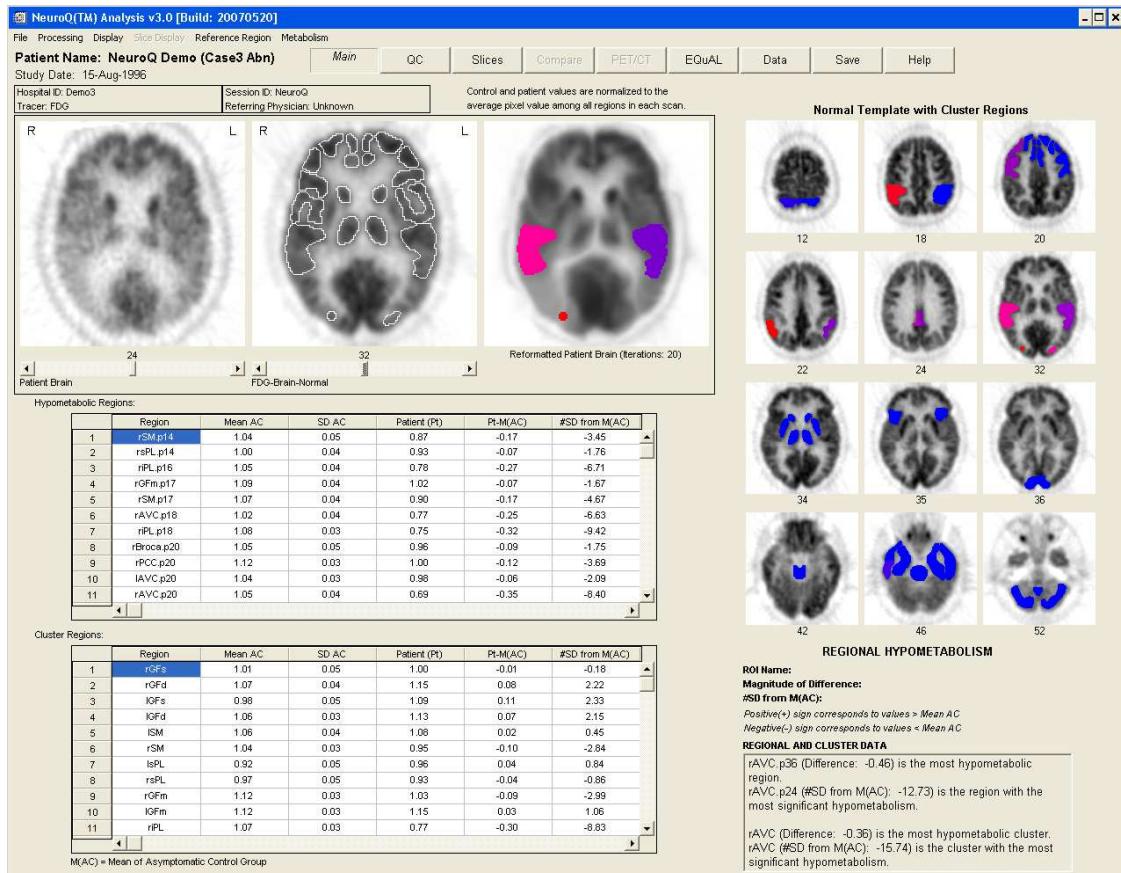

- 5) For the most standard use of the Program (i.e., comparing an individual scan from the end-user's site to NeuroQ's built-in database), it is recommended to use 20 iterations, and this is the only option that normally will ever need to be selected. The other choices in the Iterations pull-down menu (1, 2, 5, 10 and 15) have been retained in order to allow flexibility to use the tool in other ways: for example, 1) rapid testing of software operability by selecting a small number of iterations, 2) processing a batch of scans acquired at the end-user's site to create a new database with whatever number of iterations is desired, 3) sequential use of the reiteration routine, such as adding another 5 iterations to a scan that had already been re-iterated 20 times in order to obtain a closer spatial fit in a case where the individual's original scan is structurally very different from the normal template scan, 4) various research applications, etc.
- 6) Once the Reformat option has been selected, an information box will be displayed informing you of the number of iterations you have selected.

- 7) Click on the OK button and the patient's study will be reformatted to align with the normal template. On a current processor (1.7GHz) the reformatting will take approximately 2-3 minutes.

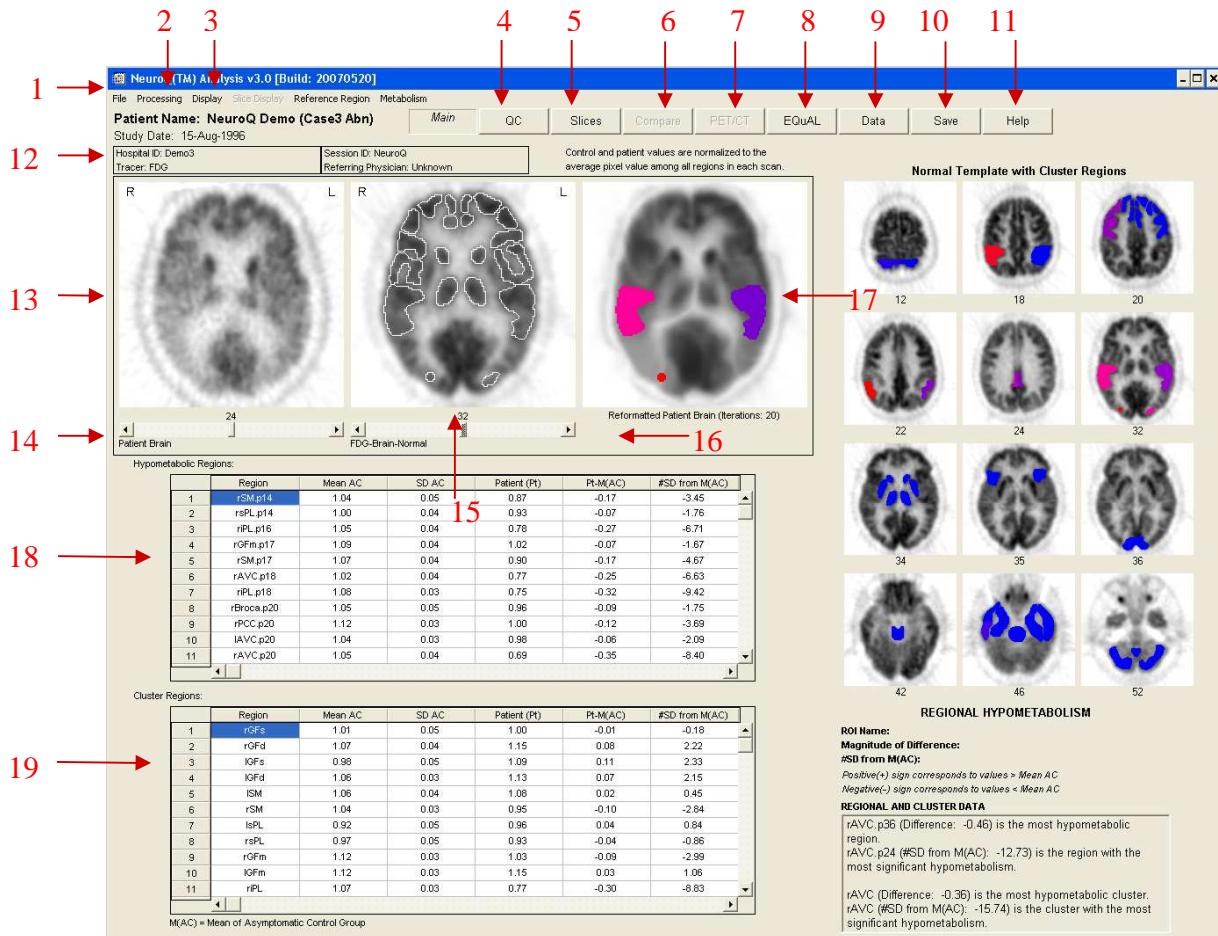

- 8) Once the study is reformatted the final quantitative analysis output will be displayed which is shown below.

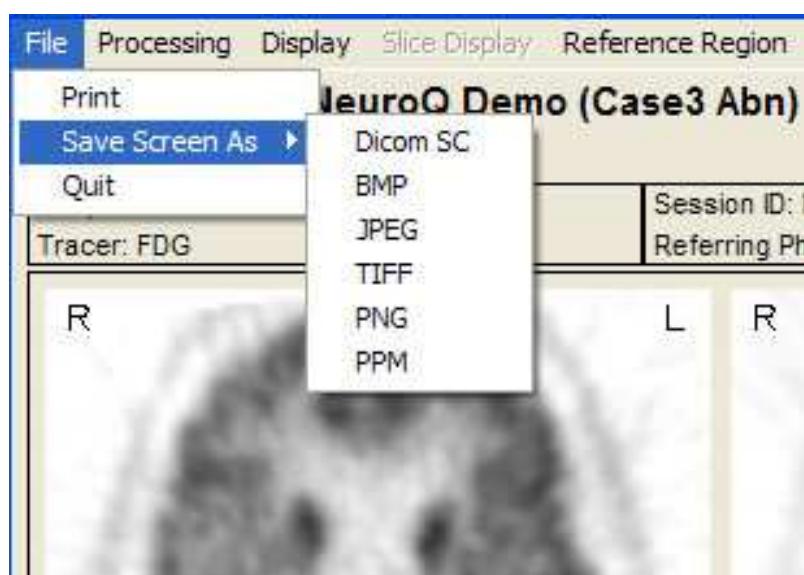

The left side of the window contains the “**NeuroQ™ Analysis**” screen and the right side contains the “**NeuroQ™ Display**” screen. These displays are defined below.

- 9) Note: There is a possibility of 3 output files that can be created from the processing of the NeuroQ study if the user selects to save the files. All of these files will be saved in the patient’s folder which contains their imaging data. The files are as follows:
- A file called NeuroQ Review File which contains the processed data for the patient using the indicated number of iterations. When you enter the program the next time you can select just this file which will show the results for that patient with the number of iterations selected without having to reformat the patients study again.
 - A file called patientname_ROIdata.dat which contains the information related to the region of interests generated during the processing.
 - A file called patientname_ROImean.dat which contains the mean values generated from the ROI analysis.

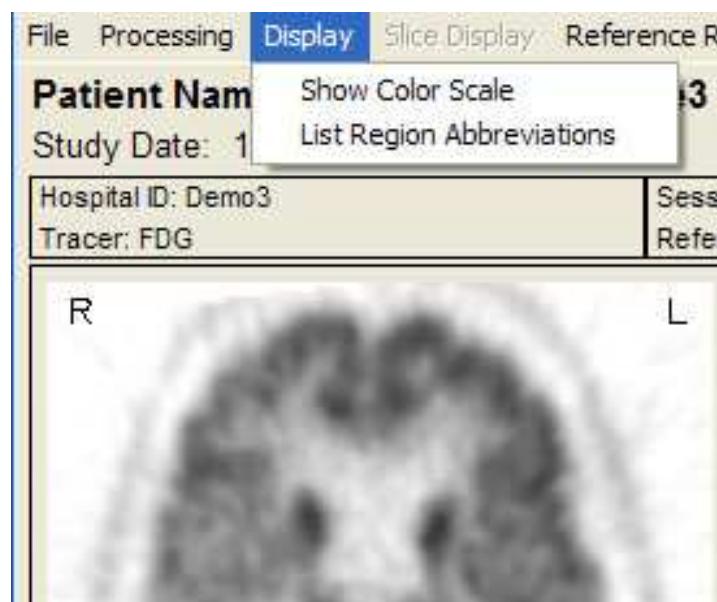

NeuroQ™ ANALYSIS SCREEN (Left Side)

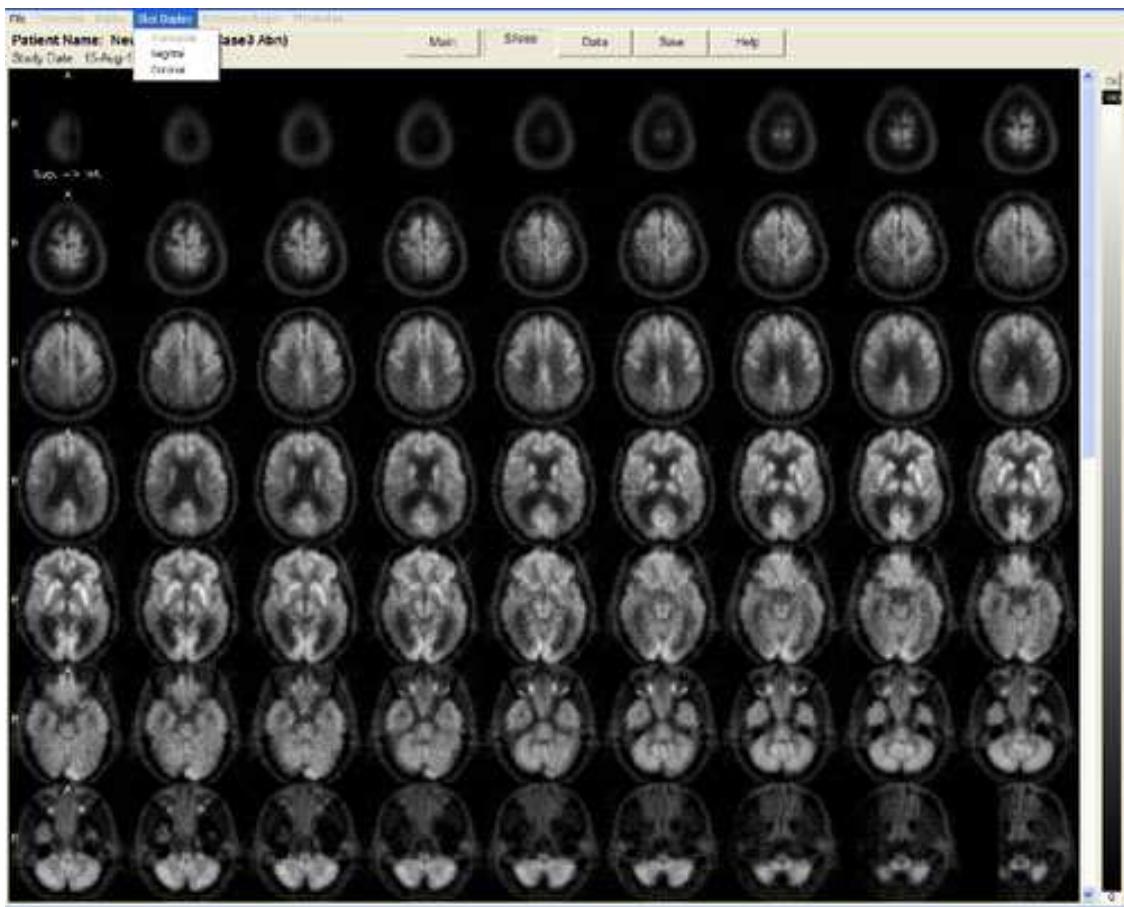

- File Menu – this allows the user to print the current screen, save the screen in various formats, and allows the user to exit. The options for save screen formats are listed to the right. Note: The DICOM Screen Capture allows the data to be saved in a format acceptable by PACS systems.

2. Processing Menu – allows user to reformat the brain, the default number of iterations is 20 and that value will be used if the Reformat option is selected from the Processing drop down list. This processing step is described above in the Processing section.
3. Display Menu – the display menu allows you to display the Color Scale and a list of region abbreviations. The options are shown below.

- The screenshot shows a 'Color Scale' dialog box. It displays a color gradient from blue to red. The Y-axis is labeled '#SD' and has values from 0.69 to 4.80. The X-axis is labeled 'Mean AC - Patient' and has values from 0.05 to 0.35.
- a. "Show Color Scale" provides a legend of the two-dimensional color coding. The number of Standard deviations is listed on the Y axis and the % below the mean normal value is listed on the X axis.
 - b. "List Region Abbreviations" will list the various abbreviations used in the application along with their meaning, i.e. rAVC = right Associative Visual Cortex.
4. QC – The Quality Control screen allows the user to apply some preprocessing steps including setting axial planes limits, removing scalp activity, and performing a rigid registration. See Quality Control section below for a further description.
 5. Slices – When the Slices button is selected it will bring up a new display window which initially will display the patients transaxial slices. From the Slice Display menu item you can also select to display the sagittal or coronal slices. This display is shown below.

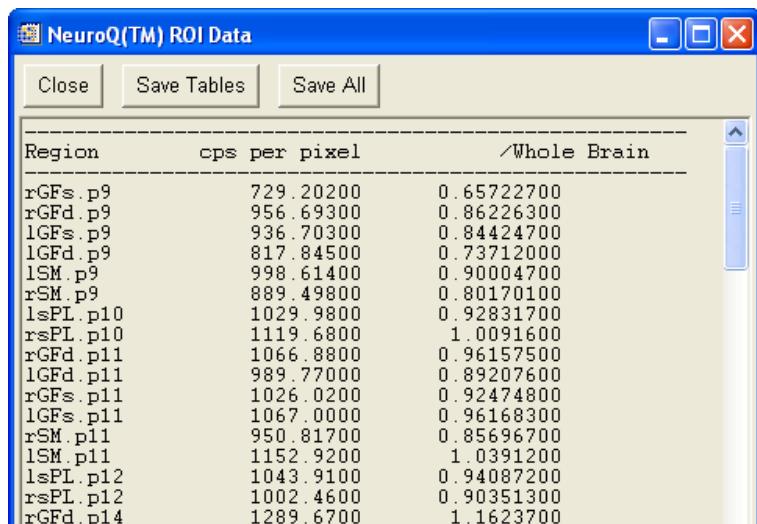

The initial display will show the patients slices in inverted grey scale. An option is provided to display the slices using other color tables by clicking on the CM (Color Map) button located above the color table bar. A list of color tables will be displayed, as shown to the left. You can select any of these color tables and the display will change to reflect this new table.

Changing top/bottom contrast – At the top of the color bar is a value of 100 and at the bottom a value of 0. If you position your cursor over one of these numbers, click left, hold down, and move the value up or down you can adjust the contrast in the image. The upper value (100) when moved down will lower the upper value producing a brighter image. The lower value (0) when moved up will increase the lower value resulting in reducing counts in the image at the low end of the scale or darken the image.

Note: to go back to the previous screen click on the Main button.

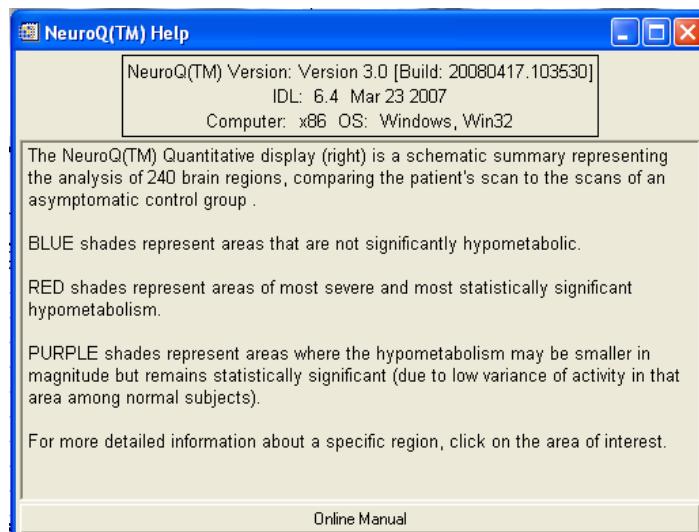

6. Compare – The compare screen allows the user to compare two studies from the same patient performed at different times. This analysis provides a Difference Image between the two studies showing which regions showed a change in hypo or hyper metabolic activity between the two studies. See the description of the Compare feature below.
7. PET/CT – The PET/CT screen allows the user to display both the PET and CT studies for the same patient and fuse those two data sets using scroll bars. See the description of the PET/CT feature below.
8. EQuAL – Reprint of article in JNM about Extent-Specified Quantified Asymmetry-of-Lobe (EQuAL) analysis which is a program that will be helpful for evaluating temporal metabolic asymmetry.
9. Data – this button will display the data screen which gives the “mean” (average number of counts per second per pixel in ROI) for each of the 240 ROIs of the patient, “norm” refers to the “mean” normalized to the average of all pixels in all ROI’s (default). This screen is shown below. This data can be saved and then imported into another application like Excel for further analysis.

The screenshot shows a Windows application window titled "NeuroQ(TM) ROI Data". The window has standard operating system controls (minimize, maximize, close) at the top right. Below the title bar are three buttons: "Close", "Save Tables", and "Save All". The main area is a table with three columns: "Region", "cps per pixel", and "%Whole Brain". The table lists 24 rows of data corresponding to the 240 ROIs mentioned in the text above. The data shows values ranging from 729.20200 to 1289.67000, with the "%Whole Brain" column showing values mostly between 0.65722700 and 1.1623700.

Region	cps per pixel	%Whole Brain
rGFS.p9	729.20200	0.65722700
rGFD.p9	956.69300	0.86226300
lGFS.p9	936.70300	0.84424700
lGFD.p9	817.84500	0.73712000
lSM.p9	998.61400	0.90004700
rSM.p9	889.49800	0.80170100
lSPL.p10	1029.9800	0.92831700
rSPL.p10	1119.6800	1.0091600
rGFD.p11	1066.8800	0.96157500
lGFD.p11	989.77000	0.89207600
rGFS.p11	1026.0200	0.92474800
lGFS.p11	1067.0000	0.96168300
rSM.p11	950.81700	0.85696700
lSM.p11	1152.9200	1.0391200
lSPL.p12	1043.9100	0.94087200
rSPL.p12	1002.4600	0.90351300
rGFD.p14	1289.6700	1.1623700

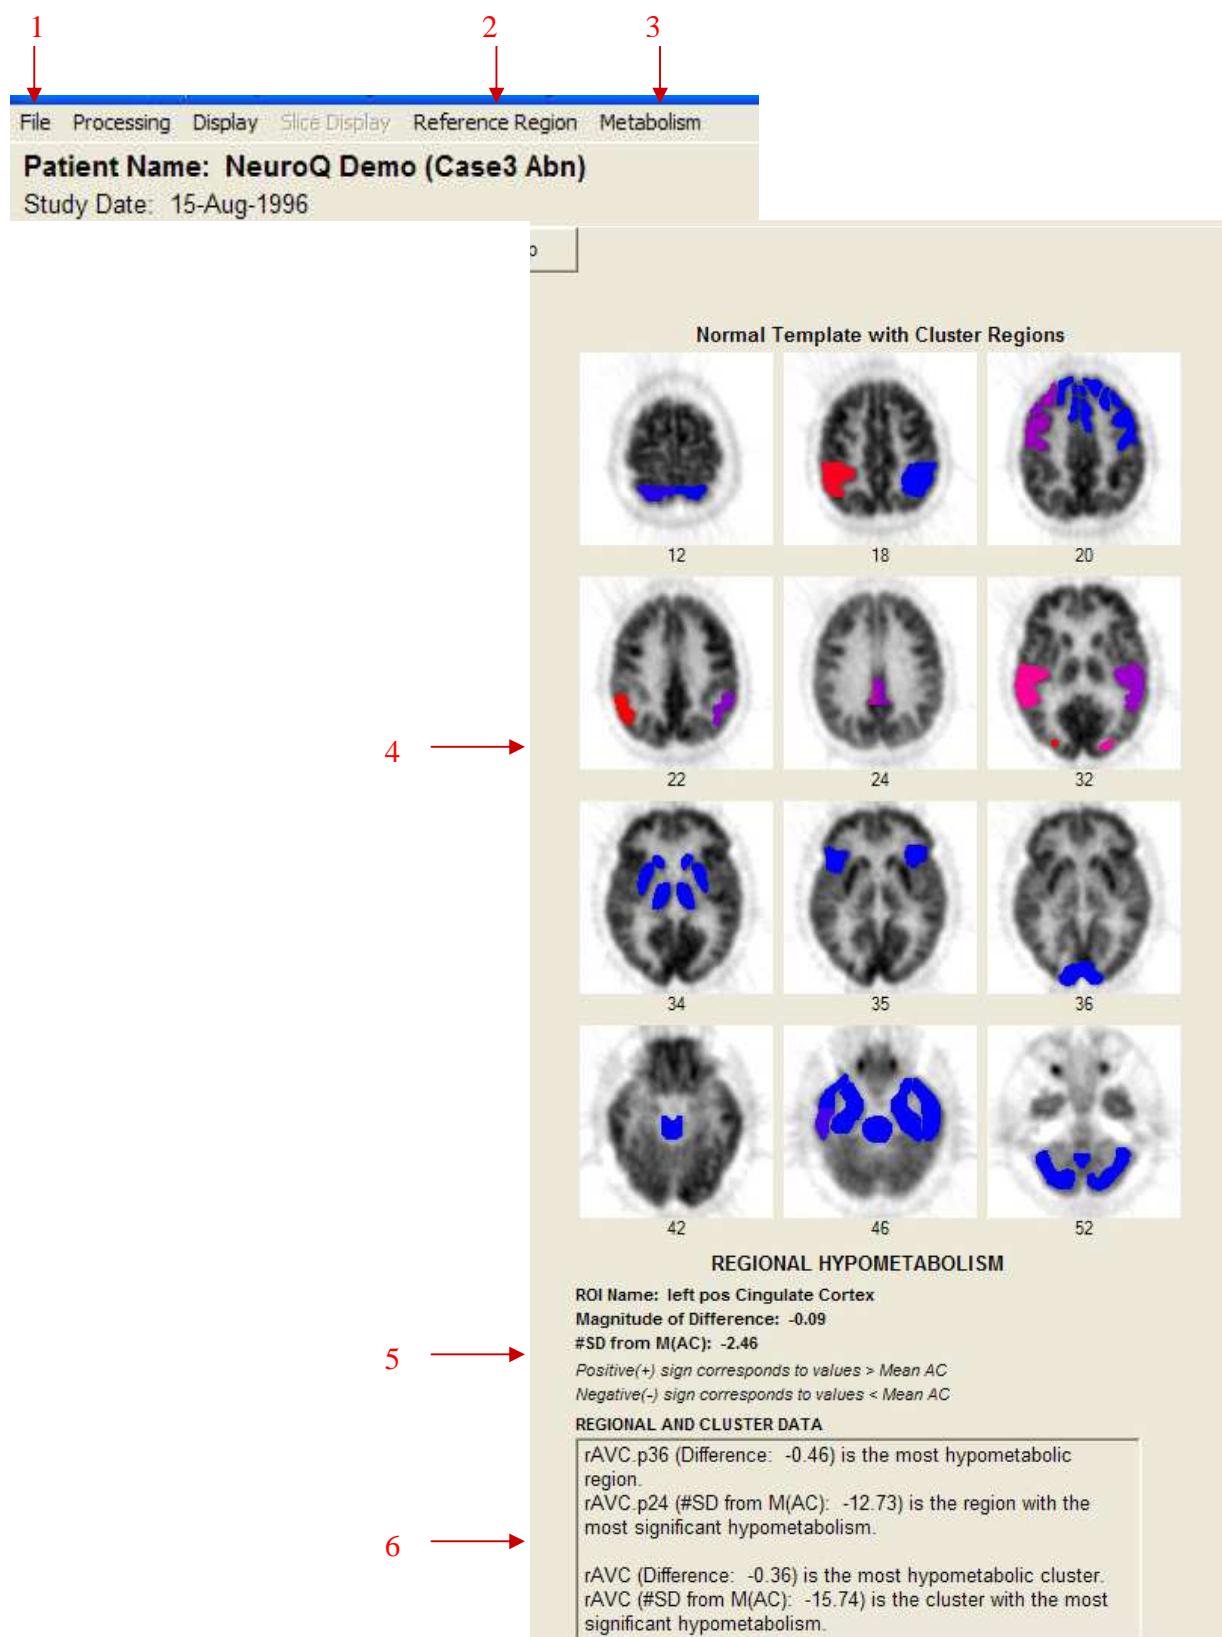

10. Save – this option when selected will save all of the reformatted data and analysis into a single file called the NeuroQ Review File. This file can then be selected and the previous reformatted data and analysis will be displayed. This avoids having to reformat the data if it needs to be displayed at another time.

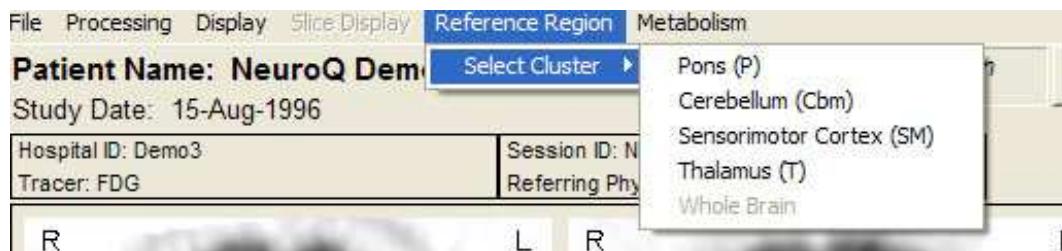

11. Help – this option will display the version number of NeuroQ and also a description of what the colors mean in the NeuroQ display.

12. Patient Information – displays patient information.
13. Patient Brain Display – displays the original patient brain transaxial slices.
14. Left Plane Slider – controls the brain plane of the above patient brain display, the current plane number is displayed above the slider, slide to the left or right to access lower or higher planes respectively.
15. Normal Template Brain – based on an archetypal normal brain with no clinical or metabolic signs of neurodegenerative disease; ROI values for each plane are drawn in with a white outline.
16. Middle Plane Slider - controls the brain plane of the normal brain display and the reformatted patient brain display at right; the current plane number is displayed above the slider, slide to the left or right to access lower or higher planes respectively, simultaneously for both displays.
17. Reformatted Patient Brain – brain is based on specified number of reiterations of the original patient brain scan; this display only appears after reiteration of brain images. All abnormal regions will be displayed in a two-dimensional coded color scale, click on the Help button for color coding explanation.
18. Table of Abnormal Regions – displays all regions having internally normalized region of interest (ROI) radiotracer uptake values falling more than 1.65 standard deviations below the mean value (in the Hypometabolic operation) and more than 1.65 standard deviations above the mean value (in the Hypermetabolic operation) for a symptomatic control group; regions are displayed in abbreviated form with the plane number after the “.p”; the last row of the table gives a total of the “Pt-M(AC)” and “#SD from M(AC)” columns.
19. Table of Cluster Values – the ROI cluster value is based on the average of the represented region across all planes where it is assessed.

NeuroQ™ DISPLAY SCREEN (Right Side)

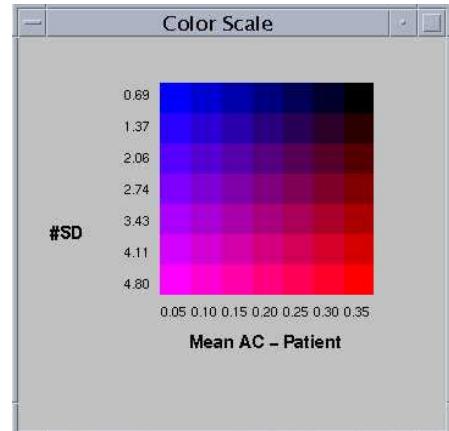

1. File Menu – user can choose the option to “Print”, “Save”, or “Quit”
2. Reference Region Menu – user can select which cluster (among “Pons”, “Cerebellum”, “Sensorimotor”, “Thalamus”, or “Whole Brain”) to base the normalization of the regions on.
NOTE: the default normalization is based on the whole brain.

3. Metabolism Menu – “Hypometabolism” displays the most hypometabolic regions and performs calculations accordingly, “Hypermetabolism” displays the most hypermetabolic regions and performs calculations accordingly, NOTE: default is “Hypometabolism”.

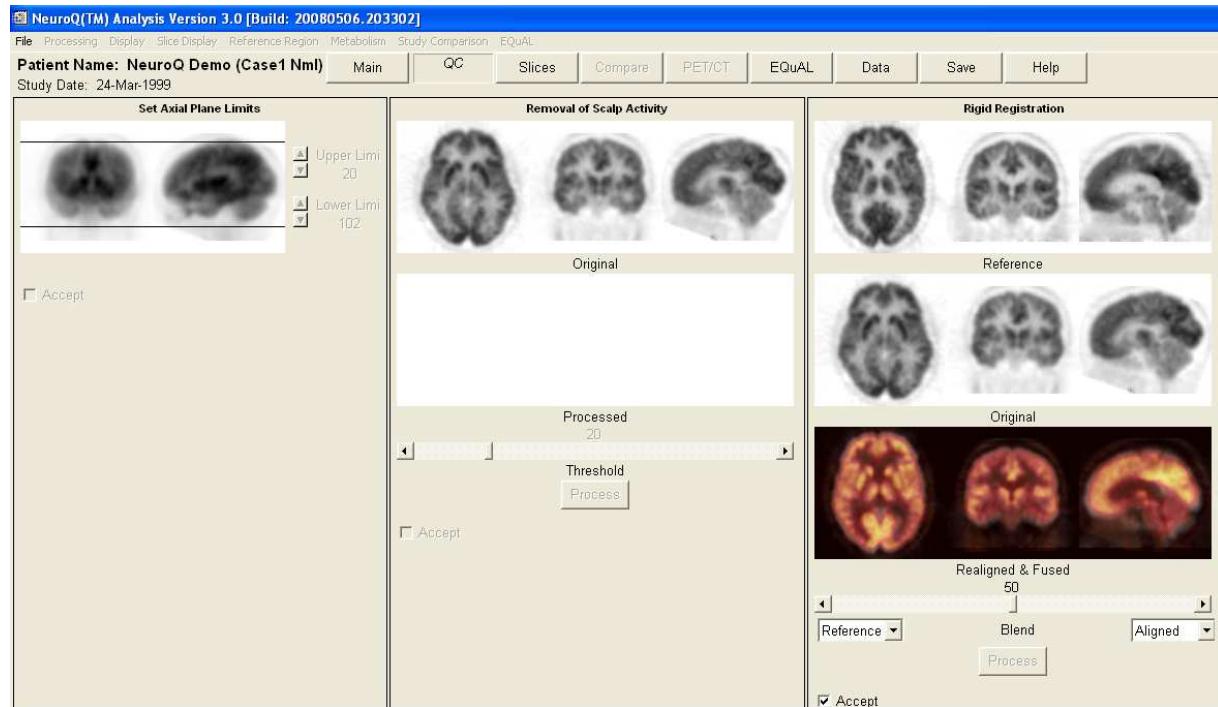

From the Display menu item you can select “Show Color Scale” to provide a legend of the two-dimensional color coding.

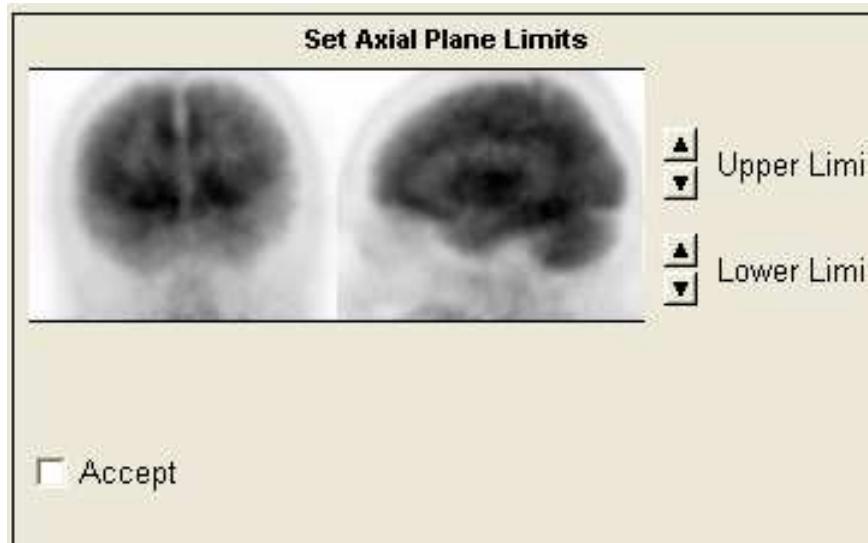

4. Brain Plane Displays – includes schematic display of each of the 47 ROI clusters, shown at the normal template planes numbered below each image. Refer to the “Show Color Scale” description for color coding explanation. Clicking on a ROI causes the full name and numerical characterization of that region to appear in the Data Display area (5).
5. Data Display – displays information based on the last ROI cluster the user clicked on.
6. Regional and Cluster Data – gives the most hypometabolic or hypermetabolic and most significant regions and clusters.

NeuroQ™ QUALITY CONTROL SCREEN

The Quality Control Screen is comprised of three sections: Set Axial Plane Limits, Removal of Scalp Activity, and Rigid Registration.

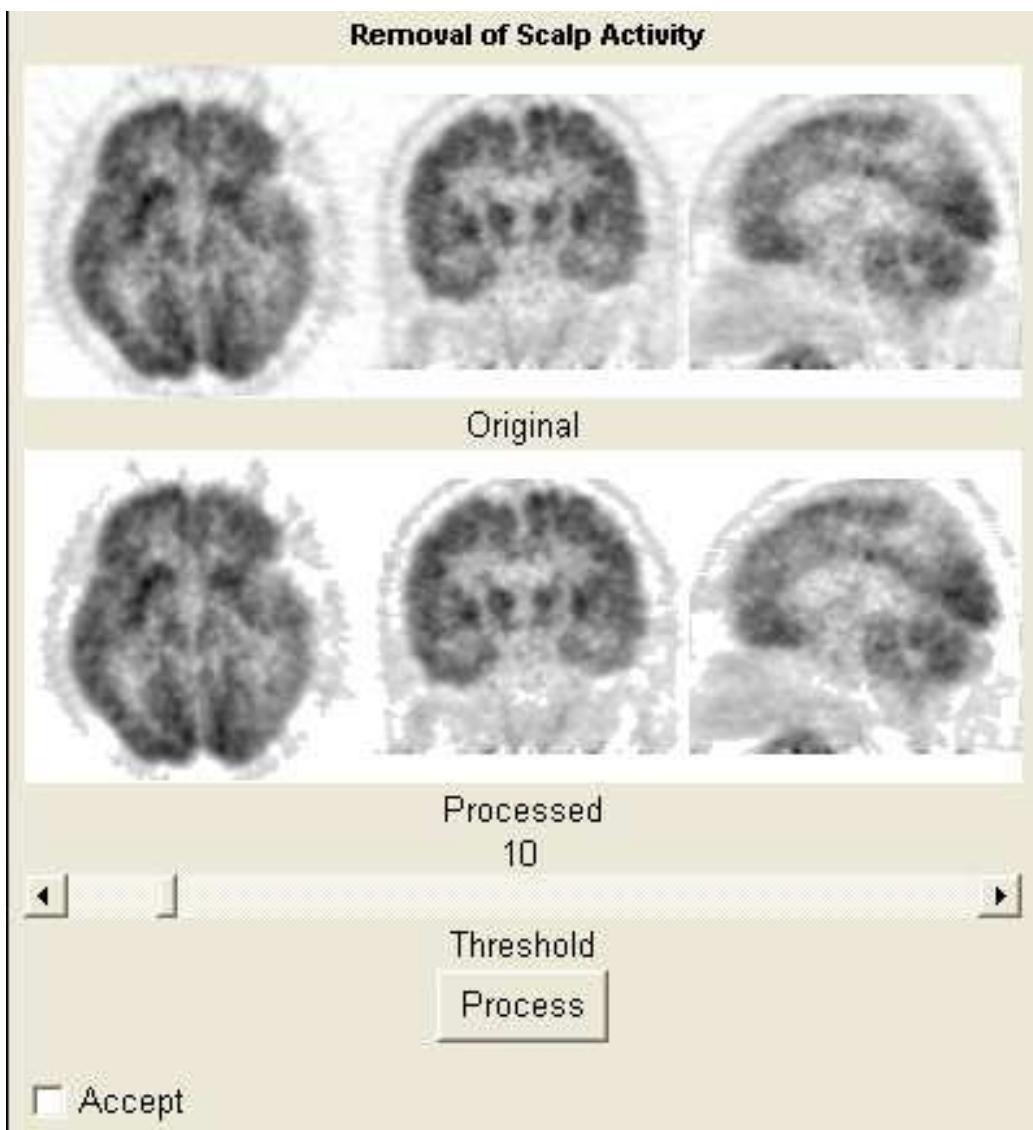

Set Axial Plane Limits

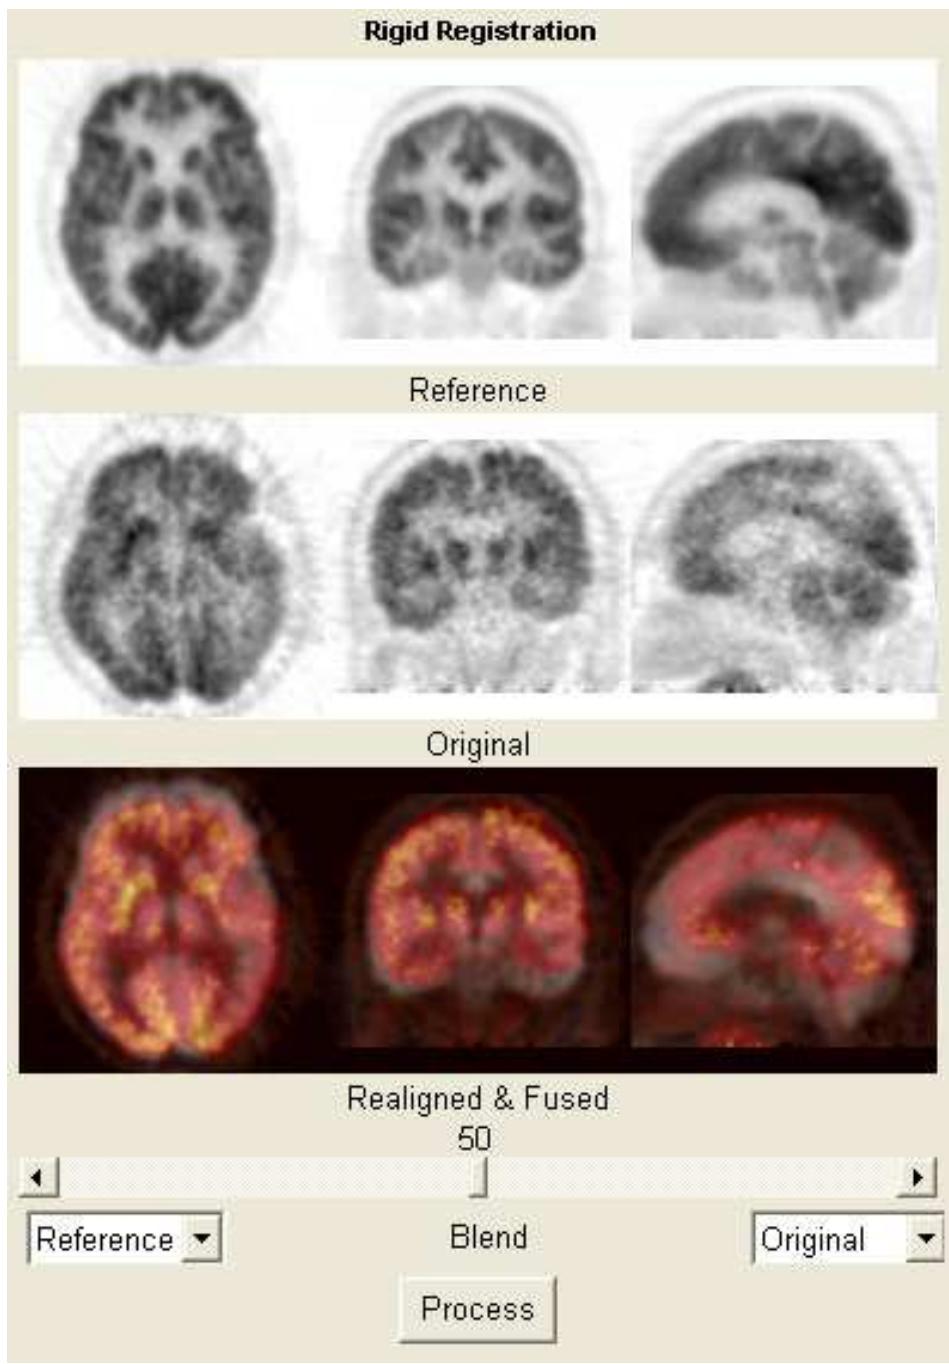

This feature allows the user to set the upper and lower limits for reconstruction by clicking the up and down arrows to move the lines. The limits can also be set by moving the cursor to a point on the image and click left to set the limit. The limits should be set so that only the brain images are included in the reconstruction. When the limits are set to the proper location check the Accept box.

Removal of Scalp Activity

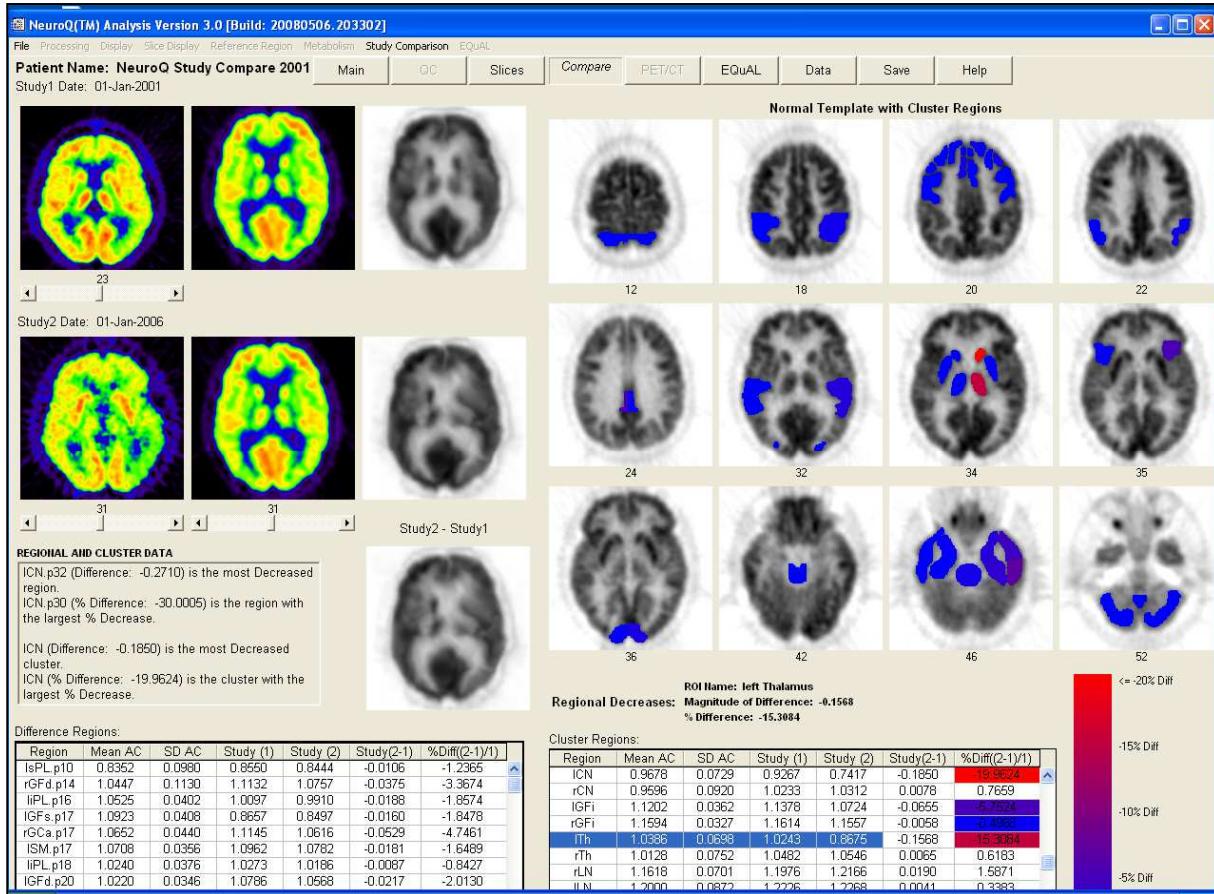

This feature allows for the removal of the scalp activity around the brain. In some cases there is excessive scalp activity which can interfere with the reformatting of the patients study to match the normal template. Move the slider bar to the desired threshold and then click on the Process button. The processed images are shown in the bottom row. Triangulation is enabled on these images by clicking left on any image and it will show you the plane for that location on the other two images. When the images are acceptable, check the Accept box.

Rigid Registration

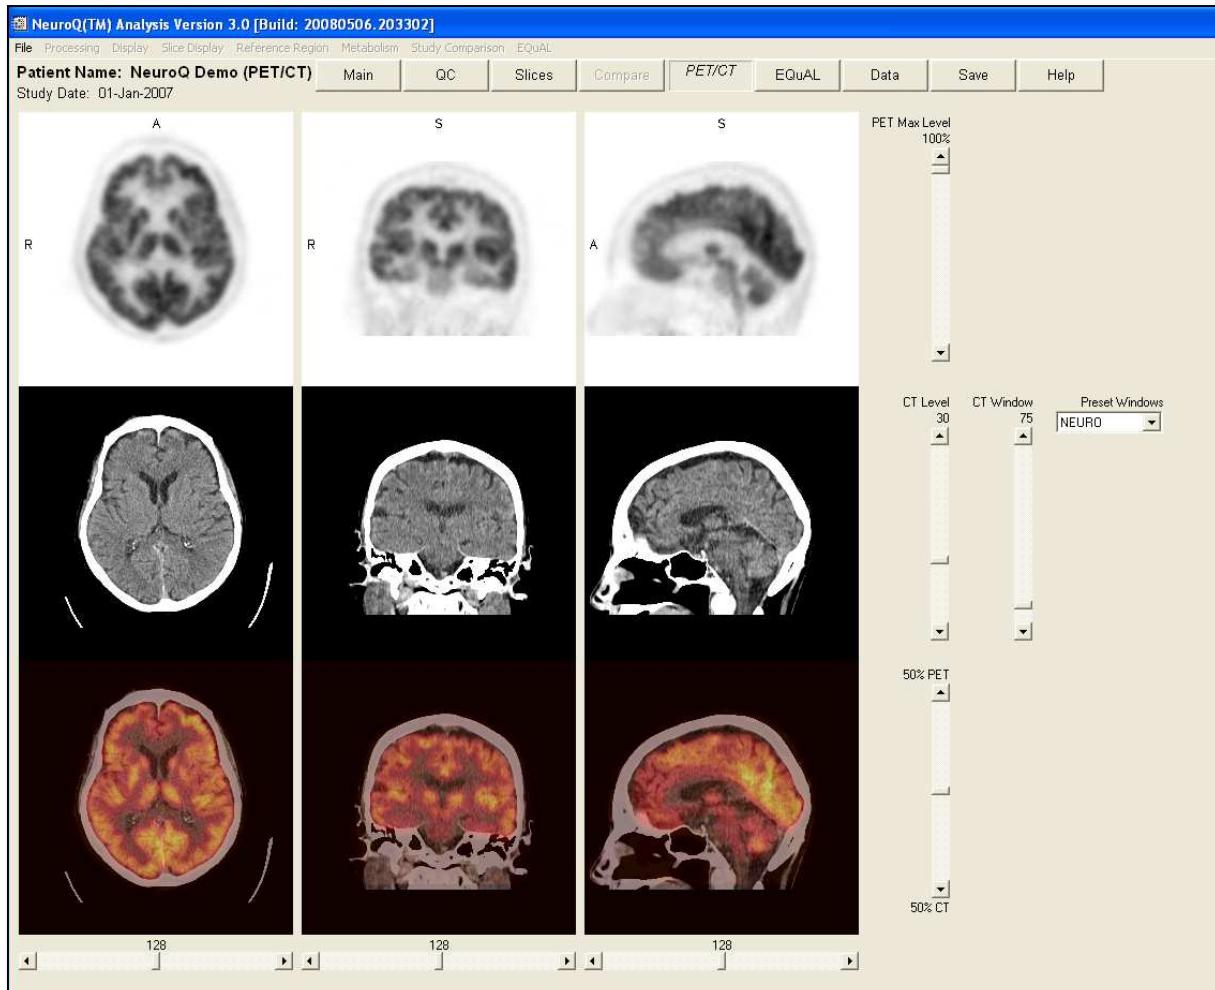

The Rigid Registration allows for applying additional registration prior to the reformatting process used in NeuroQ. This additional registration is helpful in cases where the patients head has excessive tilt. The top row shows the normal template as the reference image the middle row are the patients images and the bottom row are the fused reference and patient images after realignment. Triangulation is enabled on these images by clicking left on any image and it will show you the plane for that location on the other two images. When the images are acceptable, check the Accept box.

NeuroQ™ COMPARE DISPLAY SCREEN

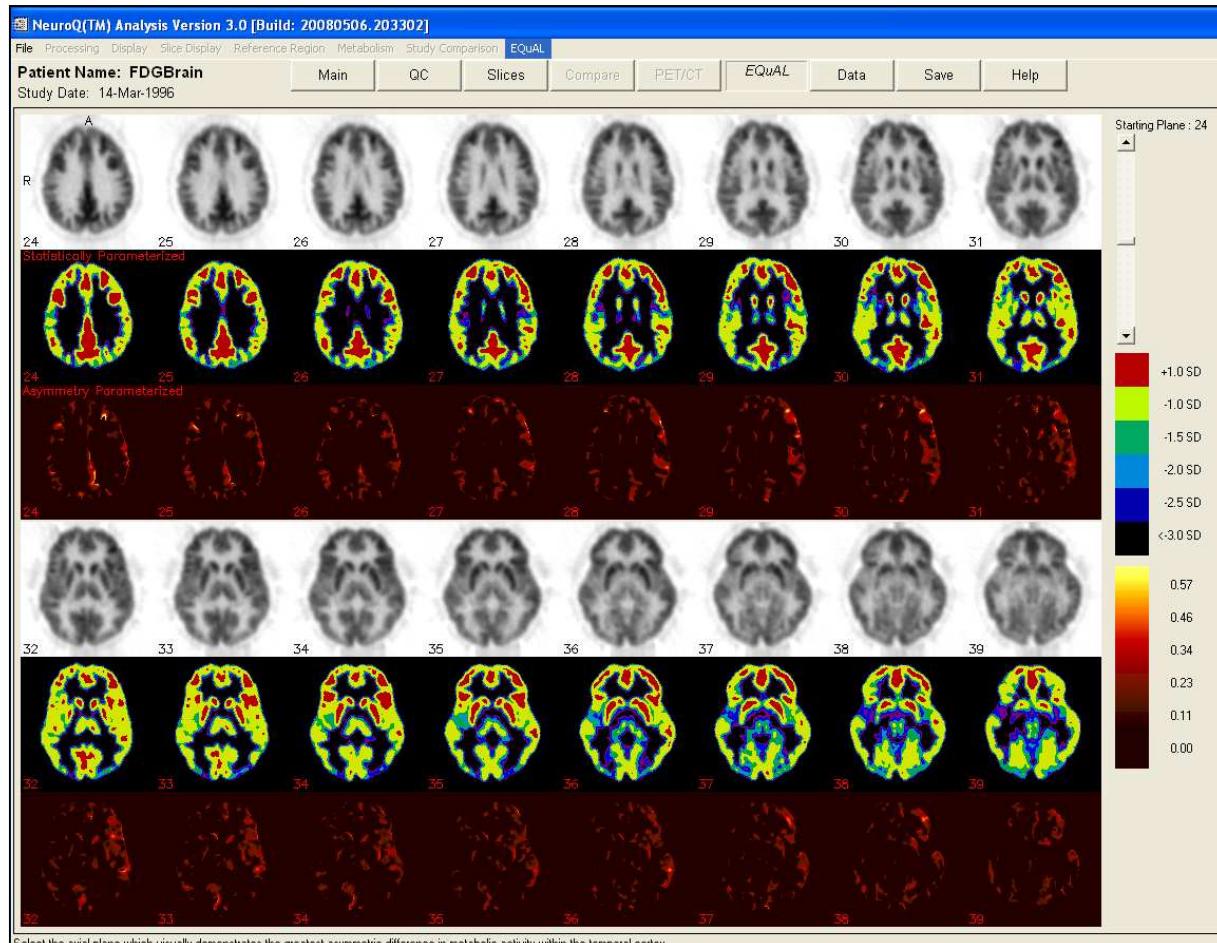

The NeuroQ Compare Screen is enabled by selecting the two studies from the MCP screen and clicking on the launch button. Once NeuroQ is launched it will show the most recent study in the main NeuroQ screen. Click on the Compare button and the Compare display screen will be shown. The oldest study is displayed in the top row, the most recent in the middle row, and the difference image is displayed in the bottom image to the right. Use the middle slider bar in the middle row to step through the planes. All images with the exception of the patient's images in the left hand column will move when the slider bar is moved left or right. The difference image shows the regions in which there is at least a 1 standard deviation difference between the original and recent study. This analysis is helpful to monitor the progression of dementia over a period of time.

NeuroQ™ PET/CT DISPLAY SCREEN

The PET/CT display allows for displaying both the PET and CT brain images from the same patient. The PET brain images are contained in the top row. The PET brain images brightness can be changed by sliding the PET Max Level slider up or down. The CT images are contained in the middle row. The CT brain images window level can be changed by manipulating the sliders for CT Level and CT Window up or down. The user also has the option picking preset windows for Neuro or Bone in the Preset Windows drop down box. The bottom row contains the fused images. The PET/CT slider bar allows the user to display only the PET (slider all the way up), only the CT (slider all the way down), or fused (slider in the middle). Various levels of fusion can be displayed by moving the slider up or down. Triangulation is enabled on the PET, CT and Fused images by clicking left on any image and it will show you the plane for that location on the other two images.

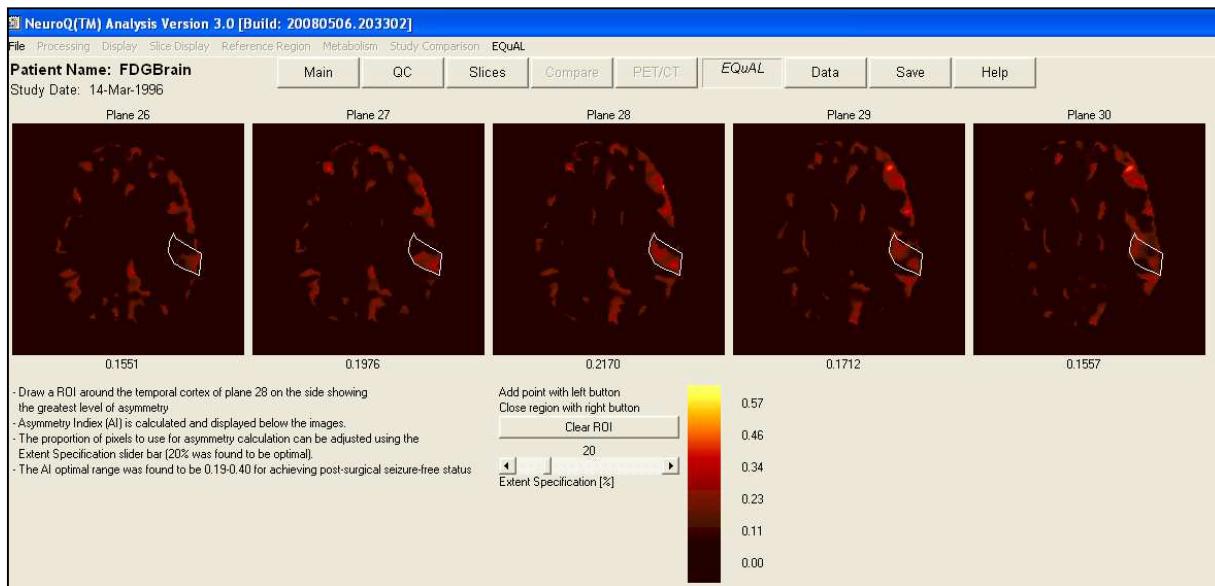

EQuAL™ ANALYSIS

The Extent-Specified Quantified Asymmetry-of-Lobe (EQuAL) Analysis will be included with the NeuroQ 3.0. This program is useful for assessing maximal temporal asymmetry over a specified proportion of the temporal lobe which may help to predict whether patients will likely be free of seizures during the years after neurosurgical resection of epileptogenic tissue.

To use EQuAL, select the patient desired and launch NeuroQ from MCP. Process the study as you would normally. Once NeuroQ is finished reformatting the data, select the EQuAL tab from the top of the screen. Select the image that the user feels best exemplifies the asymmetrical defect. Use the slider bar on the right hand side of the screen to see all slices. See example above.

Once an image has been selected, the EQuAL ROI screen will appear. Follow the on screen instructions to get the Asymmetry Index (AI).

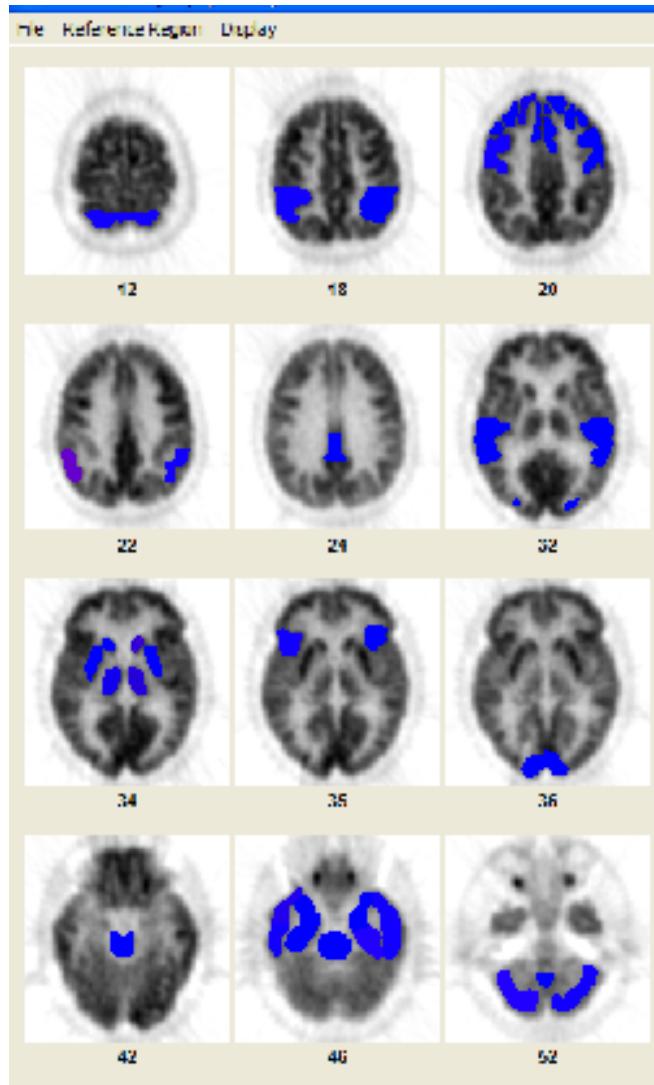

The results of this study were by Lin et. al from the Department of Molecular and Medical Pharmacology, David Geffen School of Medicine, UCLA Los Angeles was published in the May issue of the Journal of Nuclear Medicine:

Tina W. Lin, Michelle A. Kung de Aburto, Magnus Dahlbom, Lynn L. Huang, Michael M. Marvi, Michael Tang, Johannes Czernin, Michael E. Phelps, and Daniel H.S. Silverman.
 Predicting Seizure-Free Status for Temporal Lobe Epilepsy Patients Undergoing Surgery:
 Prognostic Value of Quantifying Maximal Metabolic Asymmetry Extending over a Specified
 Proportion of the Temporal Lobe. J Nucl Med. 2007 48(5): 776-782.

Description of Example Patient's

1. Demo, Case1 – Normal Case

This case demonstrates the quantitative output produced by NeuroQ when it is used to analyze a normal study. The blue areas within the cluster regions indicate that the metabolic uptake was all above the normal limit of 1.65 standard deviation. Mr. E was 71 years old when he was first referred to the UCLA Ahmanson

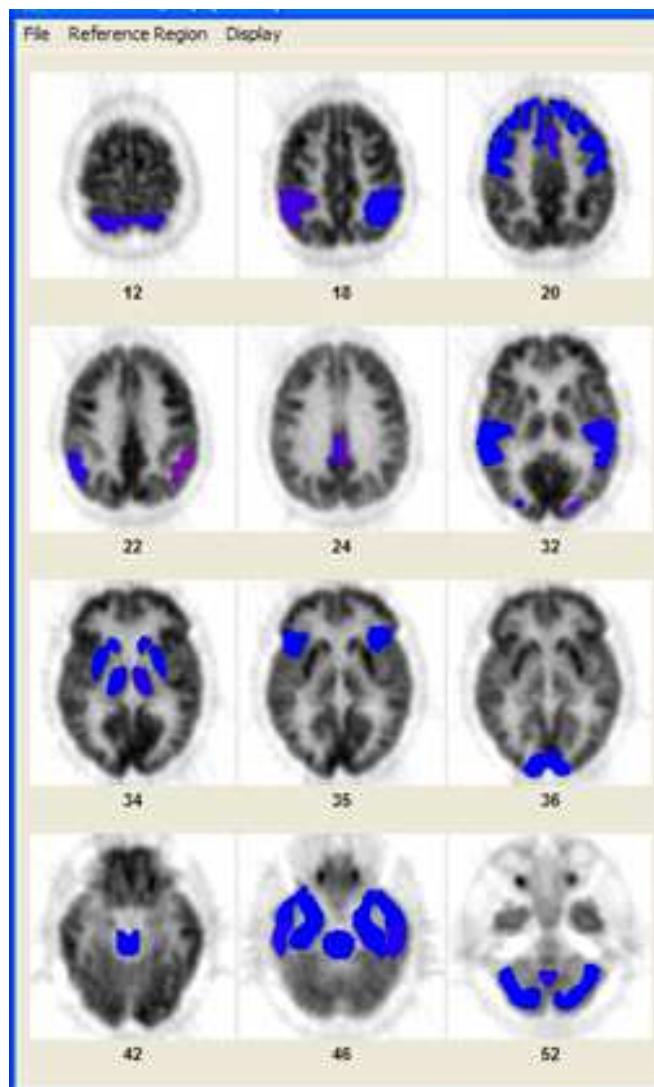

2. Demo, Case2 – Mildly Abnormal

Patient History

Mr. E was 71 years old when he was first referred to the UCLA Ahmanson Biological Imaging Division in December 2001 with concern for worsening memory. He reported that he always had a poor memory, but that over the preceding seven years, he began to notice his memory getting worse, including forgetting where he put his keys and forgetting names or faces. Mr. E had worked as a physicist for 25 years and taught physics at the University-level for the following 20 years. He reported no psychiatric hospitalizations, illness, or medication use. Mr. E had no significant medical history, including hospitalizations or illness, with the exception of prostate surgery for benign enlargement. He did not use tobacco, alcohol or other drugs and had no history of such use. His physical examination, neurologic exam and blood laboratory values (including TSH, B12, CBC, ALT and Cr) were within normal limits.

Mr. E underwent comprehensive neuropsychologic testing at the time of his first visit in 2001, and was found to be cognitively normal for his age.

Why was a PET scan obtained at this time?

This patient is seeking a diagnosis for his chief complaint, a convincing history of cognitive decline. His symptoms are unexplained by any factors identified in his history, physical or laboratory work-up. Moreover, for patients possessing his apparent high level of pre-morbid intellectual ability and education, it is common for loss of cognitive ability to be experienced, while still being able to perform at levels considered to be within the normal ranges of standard neuropsychological tests.

PET Interpretation

The scans from 2001 and 2004 each reveal mild parietal/temporal hypometabolism, more pronounced on the left (right side of image). NeuroQ™ analysis identifies mild abnormalities (purple to red shades) in parietal/temporal and posterior cingulate regions, with well-preserved metabolism in other regions (blue shades)... a pattern very suggestive of early Alzheimer's type changes occurring in this patient's brain.

The pattern of cerebral metabolism in 2004 has slightly changed since 2001. Visually, there appears to be slight interim worsening of parietal/temporal hypometabolism. [Show combined figure with arrows, on slide 3, here.] That impression is bolstered by the NeuroQ™ analysis, which shows in its plane 22 image the left parietotemporal cortex advancing to a near-red shade (12% and 4 standard deviations below normal) in 2004, from the purple shade (9% and 3 SD below normal) seen in 2001.

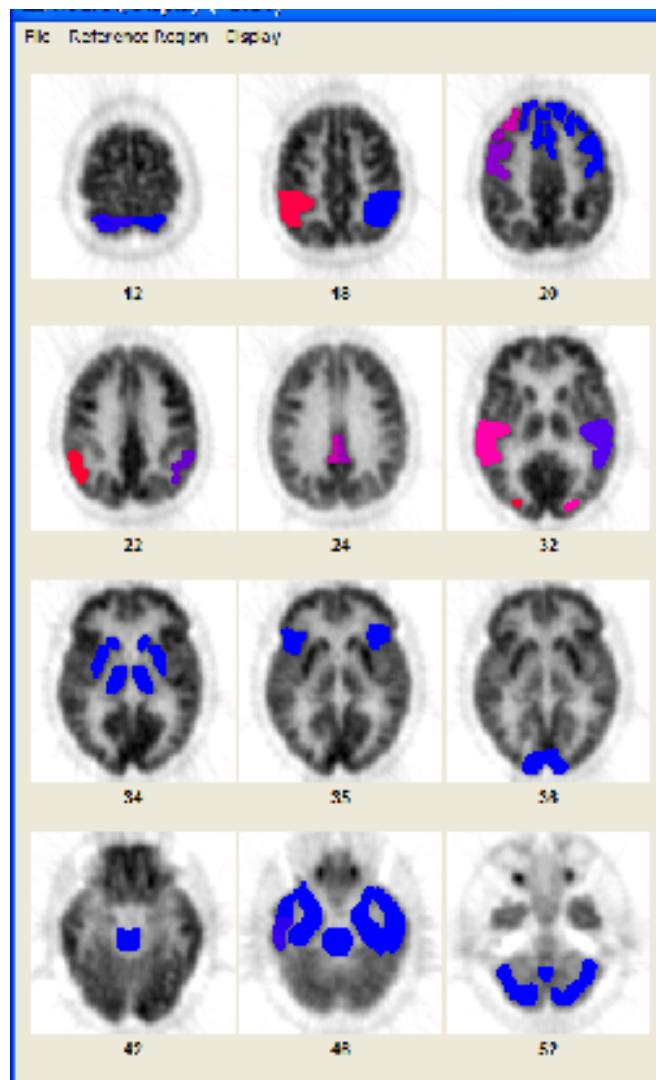

Case Summary

To summarize, at a time when conventional clinical evaluation was not sufficiently sensitive to document cognitive abnormality in this 71 year old physicist reporting memory problems, PET was already documentably (mildly) abnormal, both by visual and quantitative analyses. From 2001 to 2004, neuropsychologic performance with respect to immediate and delayed memory for word associations, contextual information, rote list learning, and complex visual stimuli declined across testing sessions, indicating “significant cognitive deterioration” within those abilities, according to the neuropsychologist. By 2004, Mr. E’s performance met criteria for “Mild Cognitive Impairment,” performing between one and two standard deviations below the mean established for his same age peers on at least 50% of the memory tasks. The combination of this clinical progression, with the posterior-predominant pattern of hypometabolism affecting especially parietal/temporal cortex is most consistent with the presence of incipient Alzheimer’s disease. Armed with the FDG-PET information, his managing physician prescribed an anti-Alzheimer’s combination regimen including both donepezil and memantine in advance of the second neuropsychologic testing session. On his current regimen, he continues to achieve 30/30 on the Mini Mental State Examination (MMSE).

3. Demo, Case3 – Severely Abnormal

Patient History

Mr. F was 63 years old when he underwent FDG-PET in August 1996 for symptoms of decreased memory, language and visual skills. The cognitive decline had been noted for at least 2 years, as had been sensory and motor deficits of his left upper extremity. Mr. F's past medical history was positive for pyelonephritis, prostatitis, and prostate surgery for benign enlargement. The patient had a history of heavy alcohol use in the past, but had discontinued drinking, and did not use tobacco or other drugs nor have a history of such use. He was a lawyer, as was his wife, and they had two small children. His physical examination, other than his neurologic exam was normal. His neurologist noted upon exam that the patient got two of three items correct regarding orientation and three of four words remembered correctly at 3 minutes, and that he had marked apraxia of the upper extremities with left worse than right, plus "mild Parkinsonism with a mask face"; cranial nerves were intact and reflexes were normal. Blood laboratory tests obtained one month prior to PET were normal, including CBC, electrolytes, BUN, creatinine, glucose, calcium, cholesterol, and liver enzymes; VDRL and TSH tests obtained the following year were also normal. The neurologist following Mr. F, an internationally recognized expert on dementia and Director of a university-based Alzheimer's Disease Center, diagnosed him with corticobasal degeneration and depression, for which he was treated with the antidepressant sertraline.

Structural Neuroimaging

1992 Brain MRI revealed "mild enlargement of the lateral ventricles... otherwise unremarkable."
1994 Brain MRI with and without contrast revealed "progression of cerebral atrophy."
1995 Brain MRI revealed "moderate generalized cerebral atrophy which is not significantly changed when compared to the scan of 1994. The scan is otherwise within normal limits."
1996 Brain MRI with and without contrast revealed "stable appearance of cerebral cortical atrophy."
1997 Head CT revealed "cerebral atrophy but is otherwise negative."

Why should the patient get a PET scan at this point in his evaluation?

Mr. F has documented cognitive decline and motor symptoms noted on neurologic examination. The symptoms are unexplained by his general history, physical examination, laboratory screen and structural neuroimaging tests, which are largely unremarkable. Although he was evaluated by a prominent dementia expert who did not suspect Alzheimer's disease, there are no tests (short of brain biopsy) documented to be as accurate as FDG-PET in the identification of Alzheimer's disease that the neurologist did, nor could do, to exclude the possibility of that now-treatable condition.

Clinical Follow-up

Mr. F. continued to progressively deteriorate with respect to cognitive and motor symptoms, also developing a seizure disorder before his death that proved resistant to medical therapy. An autopsy was performed in 2000 at the Alzheimer's Disease Center for which the patient's neurologist was Director, and the final diagnosis was "Alzheimer disease, [Braak and Braak Stage VI, CERAD definite]" with abundant neurofibrillary tangles in the hippocampus, entorhinal cortex and neocortex, as well as amyloid-beta(1-42)-staining plaques prominent throughout all areas of hippocampus, entorhinal cortex and neocortex. (Synuclein staining to check for the presence of Lewy bodies was not performed.)

Case Summary

To summarize, by the time of this PET scan, Mr. F. had undergone extensive evaluation of his cognitive and motor symptoms, including history and physical examinations by his internist, neurologic examination by a dementia expert, laboratory screening, as well as multiple brain MRI studies, two of them including contrast, and subsequently a head CT. The clinical examination led to diagnoses of corticobasal degeneration and depression, the laboratory screen was negative, and the structural imaging studies demonstrated only atrophy.

None of the above studies pointed to the presence of Alzheimer's disease, and the patient correspondingly received no treatment specific to that diagnosis. The presence of Alzheimer's disease, however, was clearly evident on both PET and autopsy examinations. PET also revealed profound hypometabolism of associative visual cortex (quantified by NeuroQ™ as falling as much as 12 standard deviations below normal metabolic levels) suggesting Lewy body involvement, which could also help to explain the prominence of the patient's central motor symptoms.

Appendix I

BRAIN PET SCAN VISUAL INTERPRETATION

Examine for (and document where appropriate):

- a) adequacy of the technical quality of scan acquisition, reconstruction, and display,
- b) presence of any evident structural abnormality, including rating the degree of atrophy as either none, slight, mild, moderate, or severe,
- c) assessment of global level of cortical metabolism, relative to the levels visually evident in basal ganglia, thalamus, and cerebellum,
- d) presence of any focal cortical abnormalities (with locations specified as left or right dorsolateral prefrontal, medial prefrontal, anterior cingulate, inferior frontal, sensorimotor, superior parietal, inferior parietal, parietotemporal, superior temporal, mid-to-inferior anterior lateral temporal, mid-to-inferior posterior lateral temporal, mesial temporal, primary visual occipital, associative visual occipital, or posterior cingulate cortex),
- e) presence of any focal non-cortical abnormalities, including in left or right caudate nucleus head, lentiform nucleus, thalamus, cerebellar cortex, midbrain, pons, and
- f) any additional findings.

The cerebral metabolic findings noted from this systematic review of the PET should be correlated whenever possible with the structural information documented on CT or MRI, with respect to cerebrovascular disease, atrophic changes, and other structural imaging findings.

Metabolic evidence of neurodegenerative processes (e.g., Alzheimer's disease, Pick's disease, and other frontotemporal dementia, dementia with Lewy bodies, dementia of Parkinson's disease, Huntington's disease) is most strongly supported by identification of areas of regional hypometabolism unmatched by structural findings (i.e., greater than could be expected for the degree of any generalized structural atrophic changes noted, and not accounted for by cerebrovascular changes).

BRAIN PET SCAN CATEGORIES FOR DEMENTIA EVALUATIONS

Scans obtained in the evaluation of cognitive impairment can be classified into one of 7 main interpretive categories (**Figure 1**, adapted from Silverman et al., JAMA, 2001; 286:2120-2127) – normal (N1) or normal except for age-appropriate atrophic changes (N2); abnormal only in a non-neurodegenerative pattern (N3); abnormal in a neurodegenerative

pattern involving posterior cortical hypometabolism consistent with presence of AD (*P1*); abnormal in a neurodegenerative pattern that includes posterior cortical hypometabolism but is nevertheless inconsistent with AD as the most likely or sole cause of cognitive impairment (*P1+*) (e.g., due to involvement of brain regions known to be preserved in AD, and/or lack of involvement of inferior parietal and posterior cingulate cortex); abnormal in a neurodegenerative pattern that is most consistent with frontotemporal dementia (*P2*), or a predominantly subcortical neurodegenerative process (*P3*).

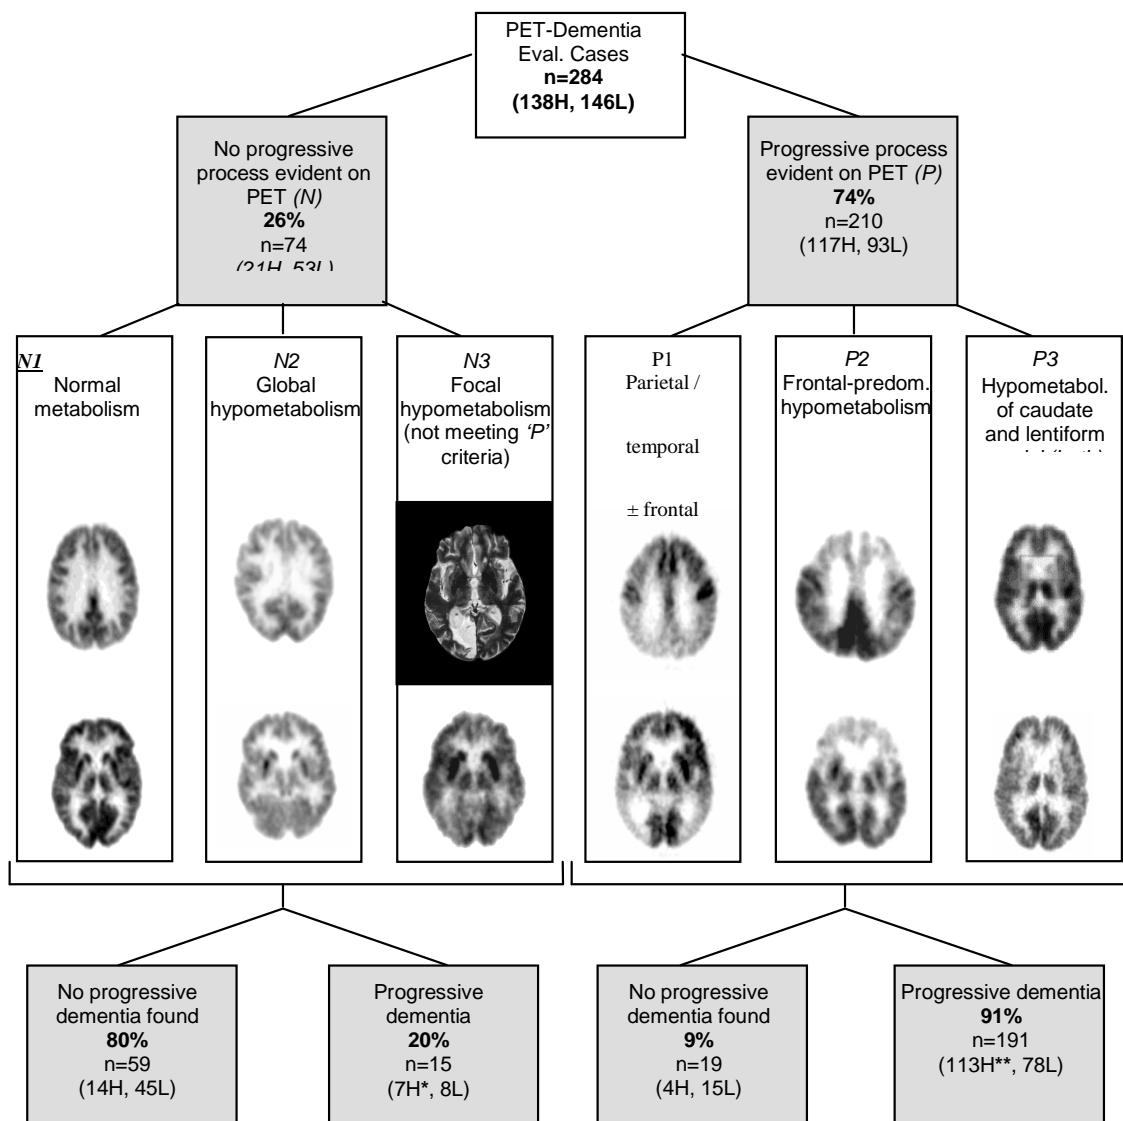

Figure 1. PET patterns and presence of progressive disease in patients undergoing evaluation for dementia.
 PET scans typical of each of six categories of cerebral metabolic patterns (designated *N*1, *N*2, *N*3, *P*1, *P*2, *P*3) are demonstrated. Images displaying *N*1, *P*1, and *P*3 patterns were acquired with a Siemens ECAT EXACT HR+ scanner; those displaying *N*2, *N*3, and *P*2 patterns were acquired with a Siemens ECAT 931 scanner. Image set in black background was acquired using a GE Signa 1.5 T MRI scanner, TR=2100, TE=80. H, diagnosis established by histopathologic examination. L, outcome established by longitudinal monitoring.

* 3 AD, 1 AD + progressive supranuclear palsy, and 3 Creutzfeldt-Jakob cases.

** 86 AD, 4 AD + Lewy bodies, 1 AD + Parkinson's disease, 1 AD + cerebrovascular disease, 1 AD + Lewy bodies + cerebrovascular disease; 7 frontotemporal, 6 Lewy body, 3 subcortical gliosis, 2 Creutzfeldt-Jakob, 1 progressive supranuclear palsy, and 1 Kuf's lipofuscinosis case.

APPENDIX II

CLINICAL BRAIN PET:

DIFFERENTIAL DIAGNOSIS OF DEMENTIA SYNDROMES

Etiology of Dementia	<u>Regional Hypometabolism Identified by FDG-PET</u>
Alzheimer's Disease	Parietal, temporal and posterior cingulate cortices affected early; relative sparing of primary sensorimotor and primary visual cortex; sparing of striatum, thalamus, and cerebellum.
Vascular Dementia	Hypometabolic foci affecting cortical, subcortical, and cerebellar areas.
Frontotemporal Dementia	Frontal cortex, anterior temporal and mesiotemporal areas affected earlier and/or with greater initial severity than parietal and lateral posterior temporal cortex; relative sparing of primary sensorimotor, posterior cingulate, and visual cortex.
Huntington's Disease	Caudate and lentiform nuclei affected early, with gradual development of diffuse cortical hypometabolism.
Parkinson's Dementia	Similar to Alzheimer's Disease, but less sparing of visual cortex. In early, untreated Parkinson's disease, basal ganglia may appear hypermetabolic.

Dementia with Lewy Bodies	Similar to Alzheimer's Disease, but less sparing of occipital cortex.

APPENDIX III

CHECKLIST TO DETERMINE WHETHER FDG-PET DEMENTIA EVALUATION IS INDICATED AND COVERED BY MEDICARE*

1. Does the patient have diminished memory and other cognitive deficits which have been present for at least 6 months, and which now impair her or his ability to function as (s)he normally would (professionally, socially, or with respect to activities of daily living)?
 Yes (continue to #2) No *PET scan is not covered.*
2. Based on history, physical examination, and blood labs, is evidence present for any of the following correctable conditions:
Depression? Substance Abuse? Malnourishment? Medication Effects? Cardiopulmonary compromise? Anemia?
Hypoxemia? Infection? Thyroid dysfunction? Renal or hepatic disorder? Glucose or electrolyte/calcium dysregulation?
 Yes (continue to #3) No (continue to #4)
3. After treatment of the above condition(s), do the deficits still persist?
 Yes (continue to #4) No *PET scan is not indicated.*
4. Does the patient suffer from Alzheimer's disease, in the judgment of a physician experienced in the diagnosis and assessment of dementia who evaluated this patient, aided by:
a) cognitive scales or neuropsychological tests, b) corroborating history from a well-acquainted informant,
c) laboratory tests (including serum B12 and TSH levels) and structural imaging (MRI or CT)?
 Yes – the physician judges the presence of Alzheimer's disease to be certain
PET scan is not covered.
 No – the physician judges the absence of Alzheimer's disease to be certain
PET scan is not covered.
 Uncertain -- the physician judges that it is uncertain whether the patient suffers from Alzheimer's disease (continue to #5)
5. Does the patient exhibit symptoms (e.g., early onset or prominence of social disinhibition, awkwardness, difficulties with language, loss of executive function) such that frontotemporal dementia is suspected as an alternative cause of the patient's cognitive deficits?
 Yes (continue to #6) No *PET scan is not covered.*
6. Is it reasonable to expect that information obtained through FDG-PET will help with diagnosis and management of the patient?
 Yes (continue to #7) No *PET scan is not covered.*
7. Has the patient previously undergone SPECT or FDG-PET for the same indication?
 Yes – the results were conclusive and the patient's condition has not substantially changed
PET scan is not covered.
 Yes – but the results were not conclusive and at least a year has elapsed
(continue to #8)
 Yes – but there have been important changes in scope or severity of the patient's cognitive deficits since then
(continue to #8)
 No (continue to #8)
8. **An FDG-PET scan is considered “reasonable and necessary” by CMS.** The patient should be referred to a facility accredited to operate Nuclear Medicine equipment and the scan should be read by an expert with experience interpreting PET scans for the evaluation of dementia.

To request a color-coded electronic copy of this Checklist, e-mail Dr. Dan Silverman at uclasomdan@yahoo.com.

APPENDIX IV

USING CLINICAL BRAIN PET FOR EVALUATION OF DEMENTIA

Indication: Changes in memory, language function, personality, or behavior -- noted by the patient, friends and family, and/or physician – for which the etiology is not evident, or the symptoms have not been reversed, within a reasonable period of time after initial presentation.

Acquisition Protocol: ^{18}FDG (10 mCi for 2D acquisitions, 3.5-10 mCi for 3D acquisitions) administered i.v., 40 min uptake period with eyes open in dimly lit quiet room; followed by transmission and emission scans, reconstructed with attenuation correction.

Interpretation: A pattern of focal cortical inhomogeneities on PET, all accounted for by areas of infarction on MRI, implies dementia secondary to cerebrovascular disease, which also often affects subcortical structures. A pattern of focal cortical inhomogeneities on PET unmatched by MRI findings is consistent with a neurodegenerative disorder (e.g., Alzheimer's disease, Pick's disease, other frontotemporal dementia, dementia with Lewy bodies, dementia of Parkinson's disease, Huntington's disease, Creutzfeldt-Jacob disease, or progressive subcortical gliosis – see Table on page 1, for differential diagnostic considerations.)
